

Chronicle: The Woman Who Wrote the Code for the Moon

In the history of software development, some names are legendary. While many people think of Linus Torvalds, there is a woman whose work was even more critical for humanity. Her name is **Margaret Hamilton**. She was a brilliant computer scientist and a pioneer in the "old school" of programming.

Margaret was a visionary. In the 1960s, she was a young woman with a sharp mind and a very professional appearance. She was **determined, disciplined, and extremely organized**. She worked at MIT, and her personality was characterized by a relentless focus on error detection. She did not just write code; she created systems to prevent disasters.

In 1969, during the Apollo 11 mission, her software faced the ultimate test. Minutes before the lunar landing, the computer system encountered an overflow of data. However, the mission did not fail. Why? Because Margaret **designed** the software to prioritize critical tasks. She **implemented** a robust logic that allowed the computer to focus on landing the Eagle.

Margaret Hamilton **created** the term "Software Engineering" because she wanted her field to have the same respect as hardware engineering. She **developed** the foundations of modern error handling and priority scheduling. Her contribution to our field is immeasurable.

For us, as software students at SENA, Margaret is an icon. She **proved** that logic, discipline, and a clean architecture are the keys to success. She represents the true spirit of a developer: solving complex problems with elegant and reliable code.
